# Invoice-to-GL Reconciliation | Controls Case

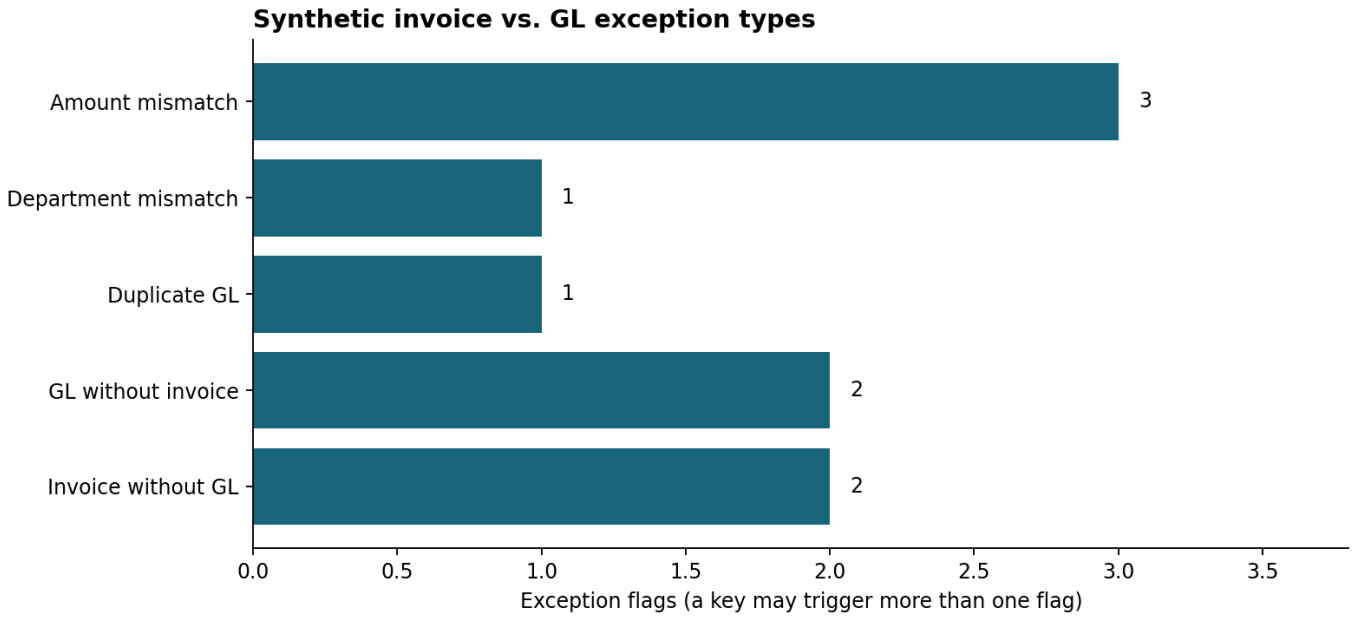
100% synthetic data | Finance Transformation case | October 2026

**72 invoices | 73 GL postings | 66 fully matched keys | 8 exception keys**

Register - GL total: $-1,310.57 (not a standalone accuracy metric)

## Control objective

Compare invoice register against ledger by ID, amount, duplicates and department.
Export a review queue instead of relying only on aggregate account totals.



## Workflow and limitations

Extract fictional AP and GL exports -> validate data -> reconcile by invoice ID ->
export exceptions -> confirm control totals -> route discrepancies to a reviewer.
Deliberately planted examples: duplicate posting; invoices missing from GL;
GL entries without invoices; incorrect amounts or departments.
Teaching case only. No real customers, measured time savings, internal process
knowledge, live ERP integration, posting automation, or accounting adjustments.
Reproduce: python src/generate_data.py; python src/reconcile.py;
python -m unittest discover -s tests -v.

Source: locally generated simulated records; full code, tests and data included in repository.
